Genetic Distance

- Naive distance measure: Hamming distance $d_0 =$ Proportion of sites at which the two sequences differ.
- Poor measure of the actual number of evolutionary changes, as a site can undergo repeated substitutions .
 $d_0(t \rightarrow \infty) = 3/4.$

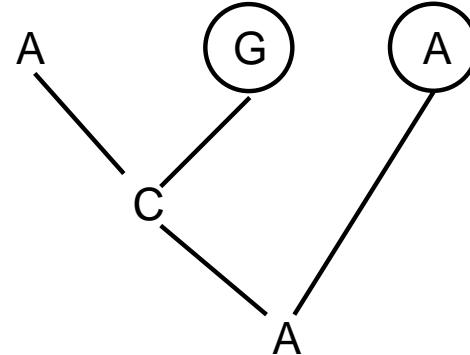

Single substitution

1 change, 1 difference

Multiple substitution

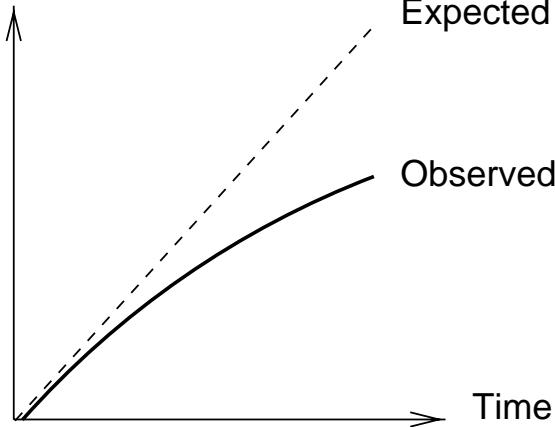

2 changes, 1 difference

Sequence difference

Expected difference

Observed difference

$$d = -\frac{3}{4} \ln \left(1 - \frac{4}{3} d_0 \right)$$

Inferring Phylogeny by Clustering: UPGMA

Definition

Distance d_{AB} between clusters A, B from individual distances d_{ab} :

$$d_{AB} = \frac{1}{|A||B|} \sum_{a \in A} \sum_{b \in B} d_{ab}$$

Algorithm

Initialisation

- Assign each sequence i to its own cluster C_i . Define one leaf for each sequence, and place at height zero.

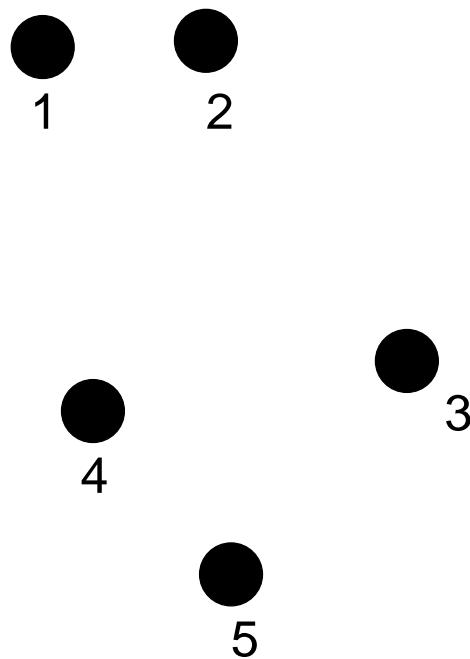

Iteration

- Determine the two clusters i, j for which d_{ij} is minimal.
- Define a new cluster $C_k = C_i \cup C_j$
- Define a new node k with daughter nodes i and j , and place it at height $d_{ij}/2$.
- Add k to the current clusters and remove i and j .

Termination

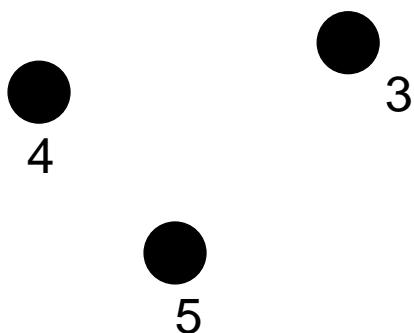

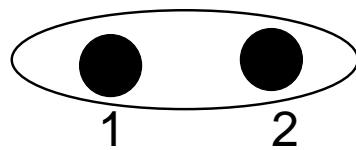

- When only two clusters i, j remain, place the root at height $d_{ij}/2$.

Inferring Phylogeny by Clustering: UPGMA

Inferring Phylogeny by Clustering: UPGMA

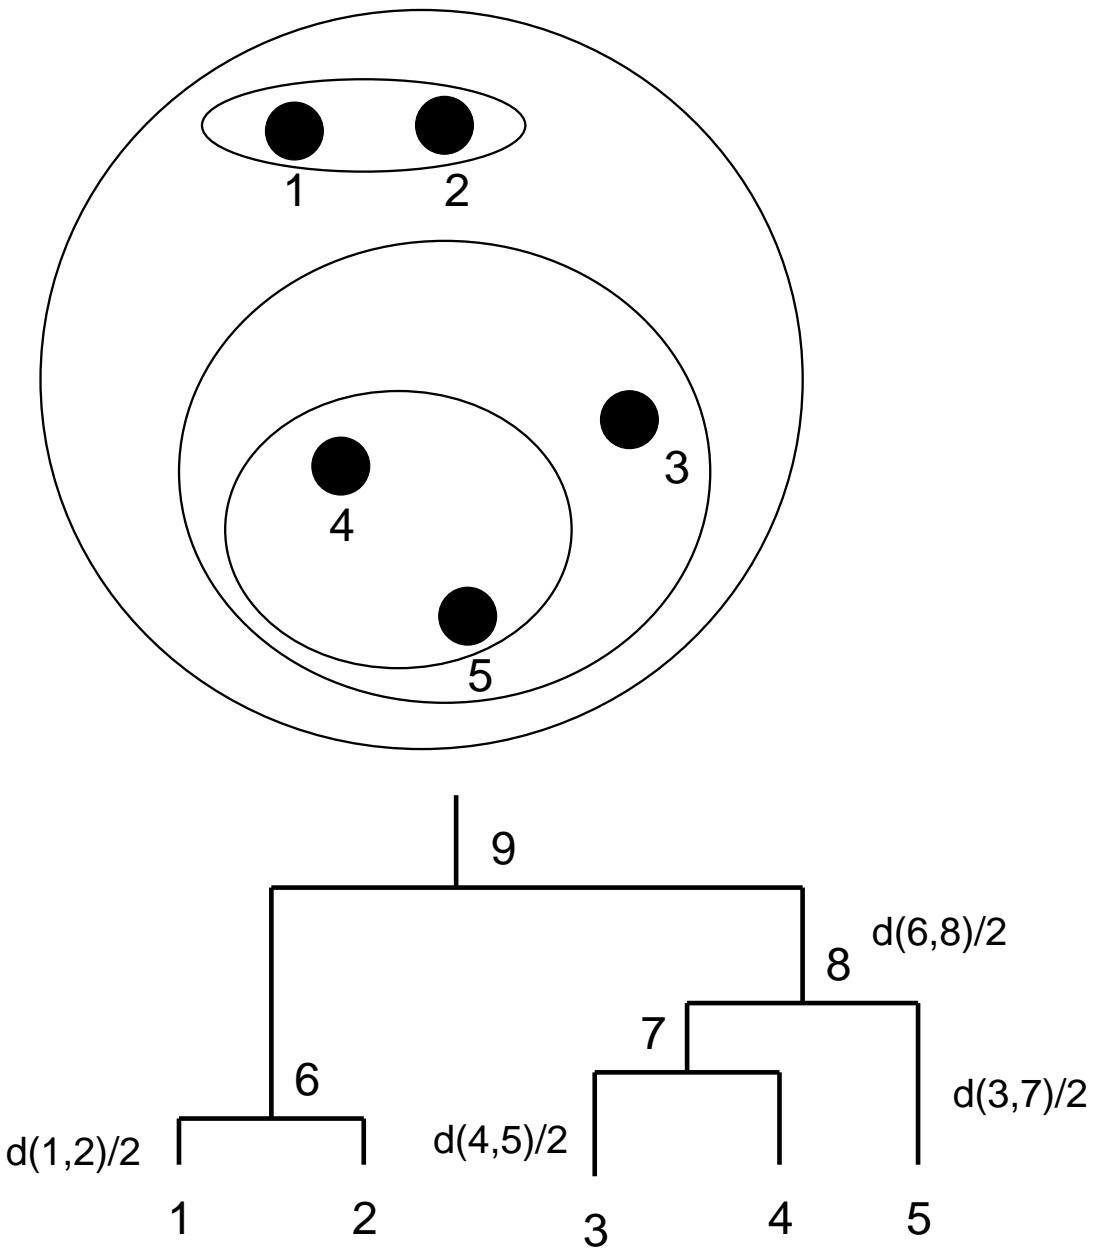

Inferring Phylogeny by Clustering: UPGMA

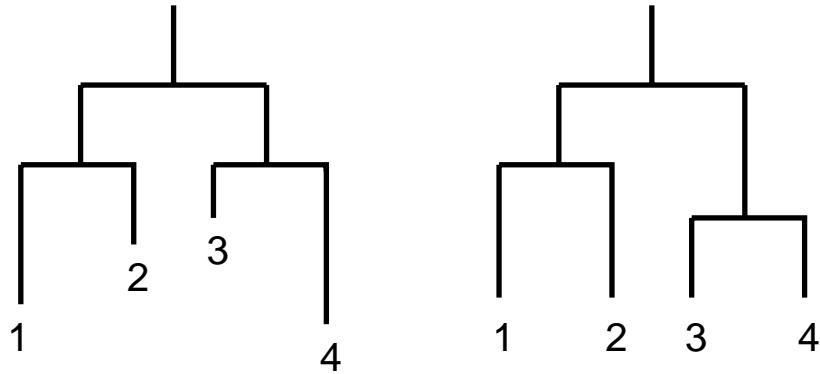

Inferring Phylogeny by Clustering: UPGMA

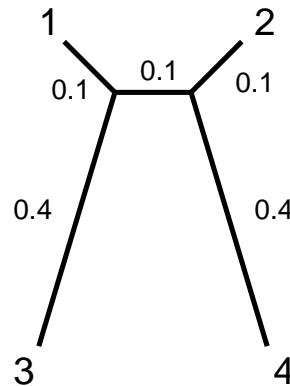

Inferring Phylogeny by Clustering: UPGMA

Limitation of UPGMA: Ultrametric Trees

Definition of corrected 'distance': $D_{ij} = d_{ij} - \bar{d}_i - \bar{d}_j$
Average distance to all other leaves: $\bar{d}_i = \frac{1}{|L|-2} \sum_{k \in L} d_{ik}$

$$\bar{d}_1 = \frac{1}{2}(0.3 + 0.6 + 0.5) = 0.7 = \bar{d}_2$$

$$\bar{d}_3 = \frac{1}{2}(0.5 + 0.6 + 0.9) = 1.0 = \bar{d}_4$$

$$D_{12} = d_{12} - \bar{d}_1 - \bar{d}_2 = 0.3 - 0.7 - 0.7 = -1.1$$

$$D_{13} = d_{13} - \bar{d}_1 - \bar{d}_3 = 0.5 - 1.0 - 0.7 = -1.2 < D_{12}$$

Inferring Phylogeny by Clustering: Neighbour Joining

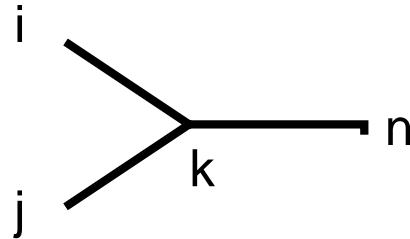

Tree metric

Non-negativity: $d_{ab} \geq 0$

Symmetry: $d_{ab} = d_{ba}$

Distinctness: $d_{ab} = 0$ if and only if $a = b$.

Triangle Inequality: $d_{ac} \leq d_{ab} + d_{bc} \rightarrow d_{ac} = d_{ab} + d_{bc}$

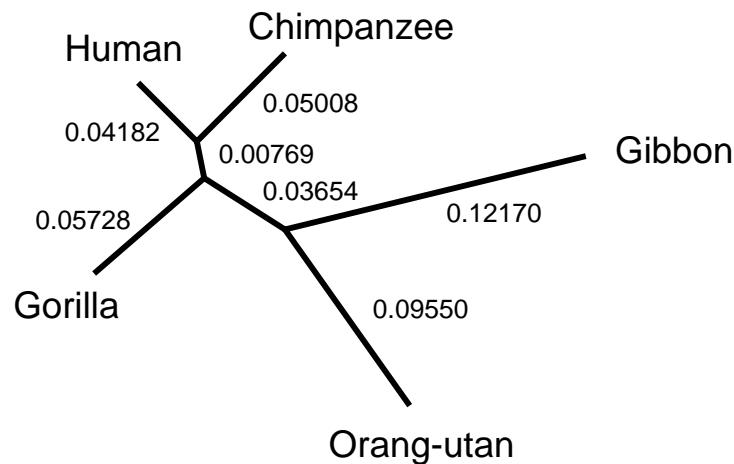

$$\begin{aligned}d_{in} &= d_{ik} + d_{kn} \\d_{jn} &= d_{jk} + d_{kn} \\\Rightarrow 2d_{kn} &= d_{in} + d_{jn} - d_{ik} - d_{kj} \\\Rightarrow d_{kn} &= \frac{1}{2}(d_{in} + d_{jn} - d_{ij})\end{aligned}$$

Iteration

- Find pair of node (i, j) that minimise D_{ij} .
 - Replace (i, j) by new node k with new distances:
$$d_{kn} = \frac{1}{2}(d_{in} + d_{jn} - d_{ij})$$
-

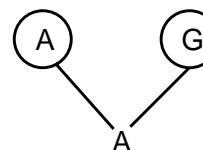

Application of Neighbour Joining

	Human	Chimp	Gorilla	Orang-utan	Gibbon
Human	-	0.0919	0.1083	0.1790	0.2057
Chimp	0.0919	-	0.1134	0.1940	0.2168
Gorilla	0.1068	0.1151	-	0.1882	0.2170
Orang-utan	0.1816	0.1898	0.1893	-	0.2172
Gibbon	0.2078	0.2160	0.2155	0.2172	-

2 changes, 1 difference

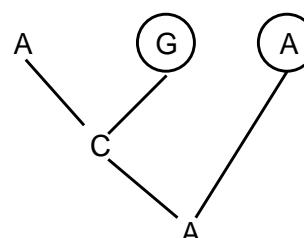

2 changes, no difference

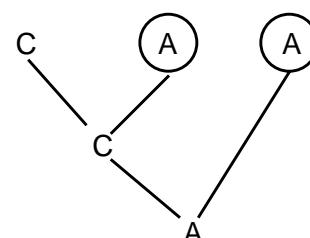

Multiple substitution

2 changes, 1 difference

Back substitution

2 changes, no difference

Objections to Distance Methods and Clustering

- Loss of Information

Sequences		Distances		
		2	3	4
1	T T A T T A A C G			
2	A A T T T A A C G	3		
3	A A A A A T A C G	3	4	
4	A A A A A A T C G	4	5	2
			1	2
			2	3

- Uninterpretable branch lengths

→ $d_{ij}^{tree} < d_{ij}^{obs}$ biologically impossible
→ Occasionally even $d_{ij}^{tree} < 0$

- The method does not optimize an objective function

Clustering methods merely produce a tree, but do not allow us

→ to evaluate the quality of the tree
→ to evaluate competing hypotheses

Evolution

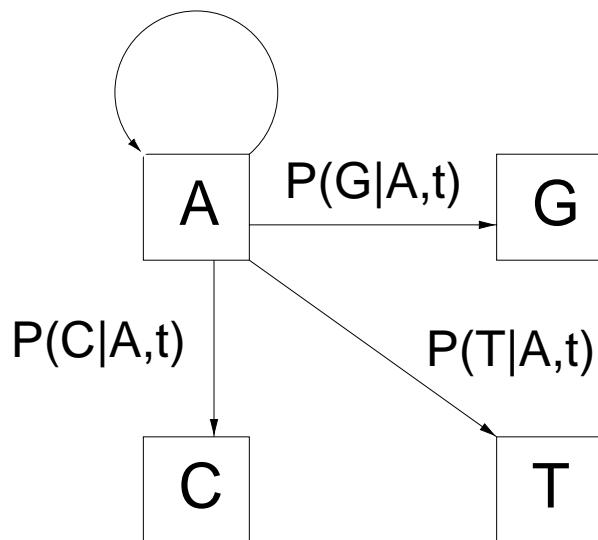

Human ... T G T A T C G C T C ...

Rabbit ... T G T G T C G C T C ...

Human ... T G T A T C G C T C ...

Chicken ... A G C A T C G T T C ...

$P(A|A,t)$

$$\mathbf{P}(t) = \begin{bmatrix} P(y(t) = A | y(0) = A) & P(y(t) = A | y(0) = G) & \dots \\ P(y(t) = G | y(0) = A) & P(y(t) = G | y(0) = G) & \dots \\ P(y(t) = C | y(0) = A) & P(y(t) = C | y(0) = G) & \dots \\ P(y(t) = T | y(0) = A) & P(y(t) = T | y(0) = G) & \dots \end{bmatrix}$$

Probabilistic Models of Evolution

$$\mathbf{P}(t) = \begin{bmatrix} P(y(t) = A | y(0) = A) & P(y(t) = G | y(0) = G) & \dots \\ P(y(t) = G | y(0) = A) & P(y(t) = G | y(0) = G) & \dots \\ P(y(t) = C | y(0) = A) & P(y(t) = C | y(0) = G) & \dots \\ P(y(t) = T | y(0) = A) & P(y(t) = T | y(0) = G) & \dots \end{bmatrix}$$

- Process is **Markov** :

$$P(y_{t+\Delta t} | y_t, y_{t-\Delta t}, \dots) = P(y_{t+\Delta t} | y_t)$$

- The Markov process is **homogenous** :

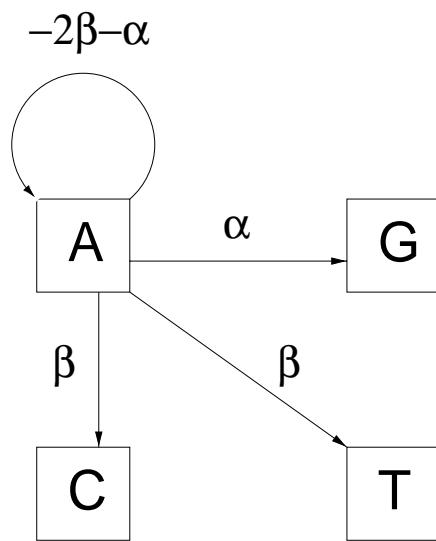

$$P(y_{t+\Delta t} | y_t) = P(y_{\Delta t} | y_0)$$

- The Markov process is the **same for all positions**
- Substitutions at different positions are **independent** of each other:

$$P[(y_1(t), \dots, y_N(t) | y_1(0), \dots, y_N(0)] = \prod_{i=1}^N P[y_i(t) | y_i(0)]$$

Transition Rates

$$\begin{aligned}\mathbf{P}(0) &= \mathbf{I} & \mathbf{P}(dt) - \mathbf{P}(0) &= \mathbf{R}dt \\ \mathbf{P}(t + dt) &= \mathbf{P}(dt)\mathbf{P}(t) = (\mathbf{I} + \mathbf{R}dt)\mathbf{P}(t) \\ \frac{d\mathbf{P}}{dt} &= \mathbf{R}\mathbf{P} \implies \mathbf{P}(t) = e^{\mathbf{R}t}\end{aligned}$$

$$\mathbf{R} = \begin{bmatrix} -2\beta - \alpha & \beta & \alpha & \beta \\ \beta & -2\beta - \alpha & \alpha & \beta \\ \alpha & \beta & -2\beta - \alpha & \beta \\ \beta & \alpha & \beta & -2\beta - \alpha \end{bmatrix}$$

Transition Probabilities

$$\mathbf{P}(t) = e^{\mathbf{R}t} = \begin{bmatrix} d(t) & f(t) & g(t) & f(t) \\ f(t) & d(t) & f(t) & g(t) \\ g(t) & f(t) & d(t) & f(t) \\ f(t) & g(t) & f(t) & d(t) \end{bmatrix}$$

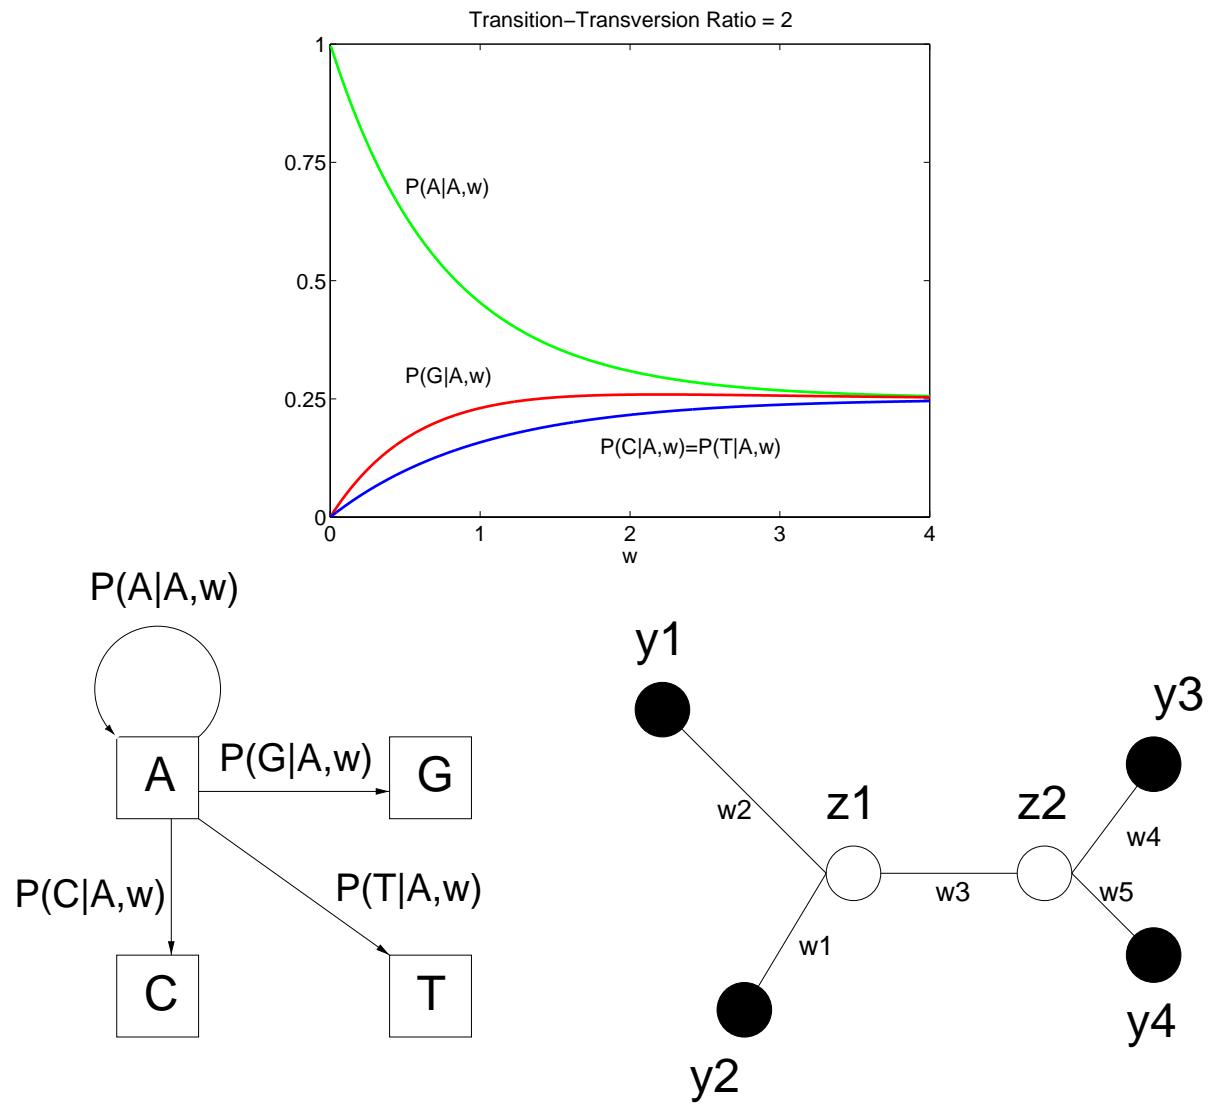

$$\begin{aligned} f(t) &= \frac{1}{4}(1 - e^{-4\beta t}) \\ g(t) &= \frac{1}{4}(1 + e^{-4\beta t} - 2e^{-2(\alpha+\beta)t}) \\ d(t) &= 1 - 2f(t) - g(t) \end{aligned}$$

Molecular time: $w := 4\beta t$

$$\begin{aligned} f(w) &= \frac{1}{4}(1 - e^{-4w}) \\ g(w) &= \frac{1}{4}(1 + e^{-4w} - 2e^{-2(\tau+1)w}) \\ d(w) &= 1 - 2f(w) - g(w) \end{aligned}$$

Transition-transversion ratio: $\tau = \frac{\alpha}{\beta}$

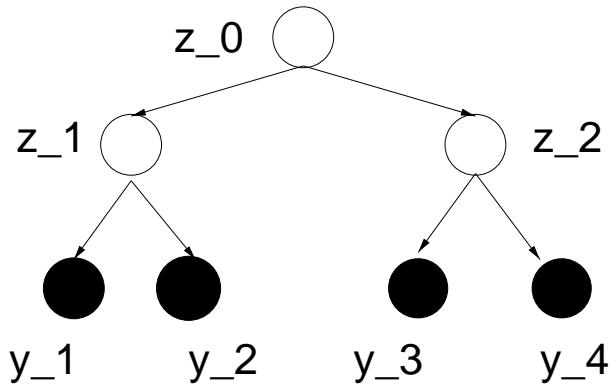

A Probabilistic Model of Evolution

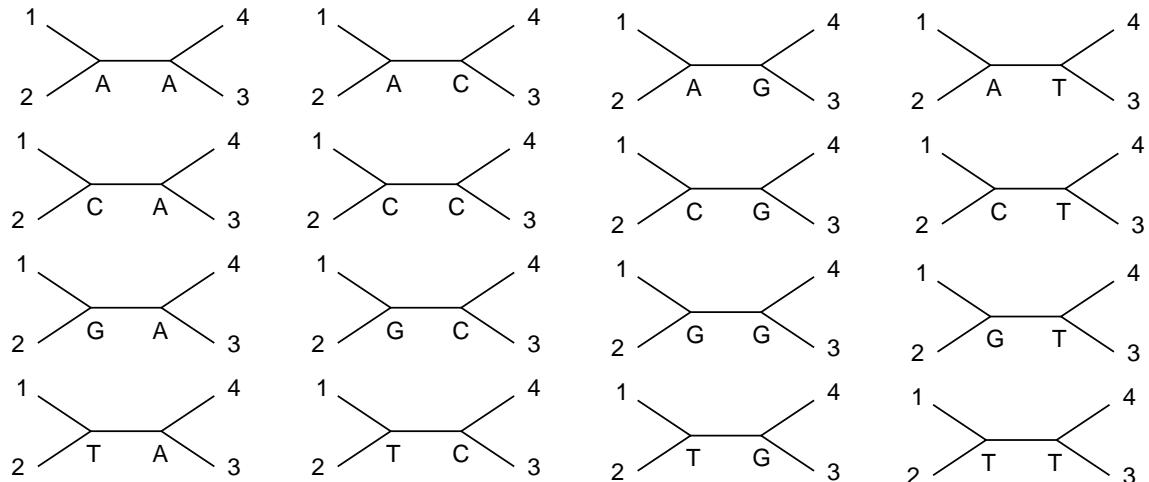

$$P(y_1, y_2, y_3, y_4, z_1, z_2 | \mathbf{w}) = \\ P(y_1 | z_1, w_2) P(y_2 | z_1, w_1) P(z_2 | z_1, w_3) P(y_3 | z_2, w_4) P(y_4 | z_2, w_5)$$

$$P(y_1, y_2, y_3, y_4 | \mathbf{w}) = \sum_{z_1} \sum_{z_2} P(y_1, y_2, y_3, y_4, z_1, z_2 | \mathbf{w})$$

Tree Likelihood: Factorisation and Marginalisation

$$P(y_1, y_2, y_3, y_4, z_0, z_1, z_2) = \frac{P(y_1|z_1)P(y_2|z_1)P(y_3|z_2)}{P(y_4|z_2)P(z_1|z_0)P(z_2|z_0)} P(z_0)$$

$$P(y_1, y_2, y_3, y_4) = \sum_{z_0, z_1, z_2} P(y_1, y_2, y_3, y_4, z_0, z_1, z_2)$$

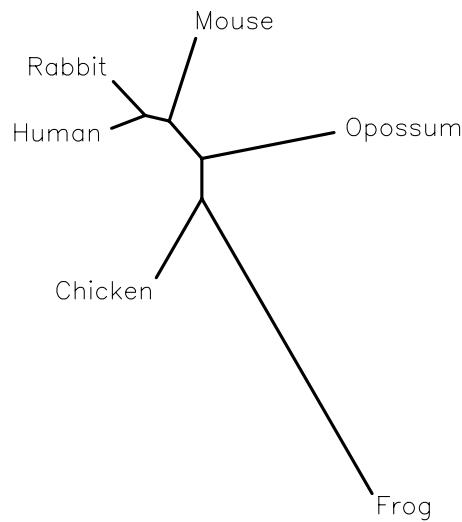

Probabilistic Approach to Phylogeny

Chicken	AG C ATCGTTCTATTTCACCGGCTCCCG
Human	TG T ATCGCTCAAGATTGCCATCGCGCG
Rabbit	TG T GTCGCTCAAGATTGCCATCGCGCG
Mouse	TG T CGTGGTCTAGATTGCCATCGCGCG
Opossum	TG T ATCGCTCTAGTTGCCAGCTCCCG

$$\mathbf{D} = (\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_N)$$

$$P(\mathbf{D}|\mathbf{w}, S) = \prod_{t=1}^N P(\mathbf{y}_t|\mathbf{w}, S)$$

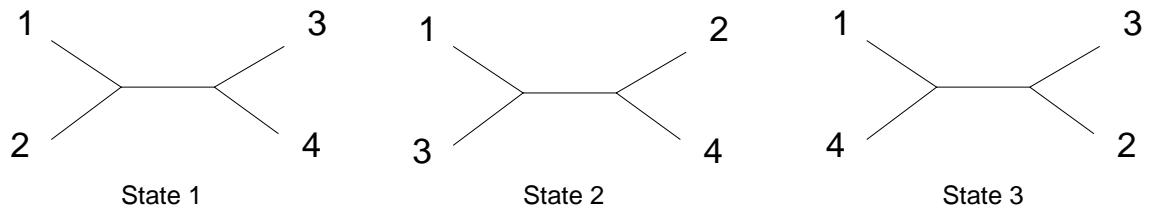

Optimise topology S and branch lengths \mathbf{w} with maximum likelihood

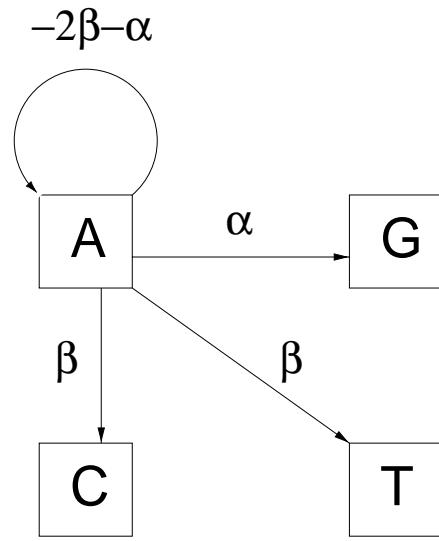

Maximum Likelihood

Maximise the likelihood of $L(S, \mathbf{w}, \mathbf{R}) = \ln P(D|S, \mathbf{w}, \mathbf{R})$

- Tree topology S

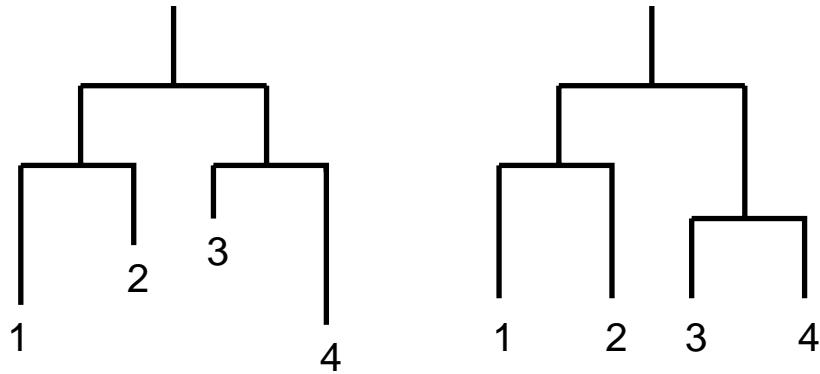

- Branch lengths $\mathbf{w} = (w_1, w_2, w_3, w_4, w_5)$
- Evolutionary parameters: Rate matrix \mathbf{R}

Hypothesis Testing

Nested models

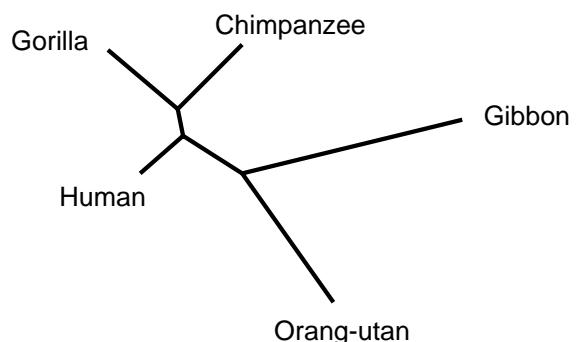

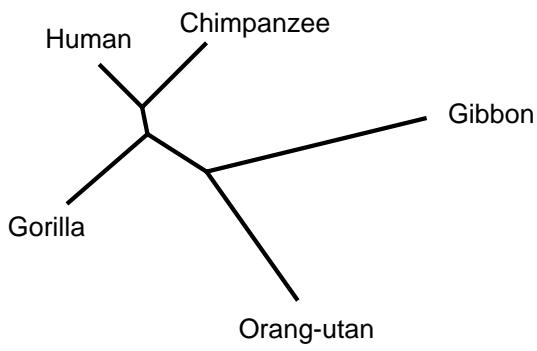

H_0 : ultrametric tree (molecular clock)

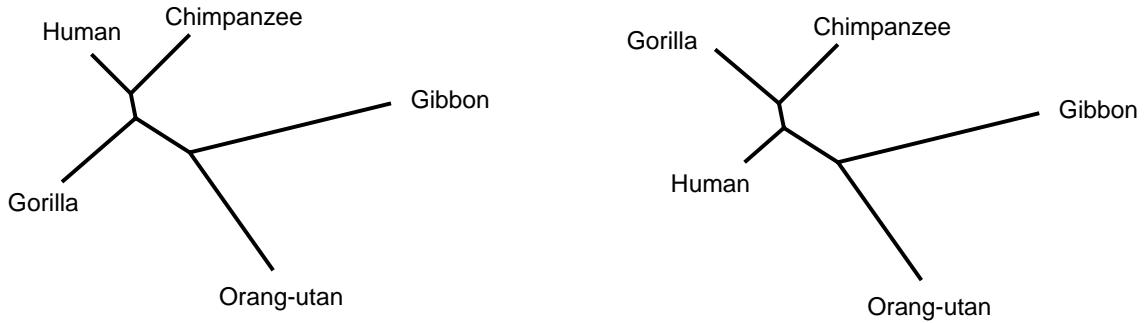

($K - 1$ constraints, $K =$ number of leave nodes).

Likelihood ratio test: $2(L_1 - L_0) \sim \chi^2_{(K-2)}$

Non-nested models

Bootstrapping

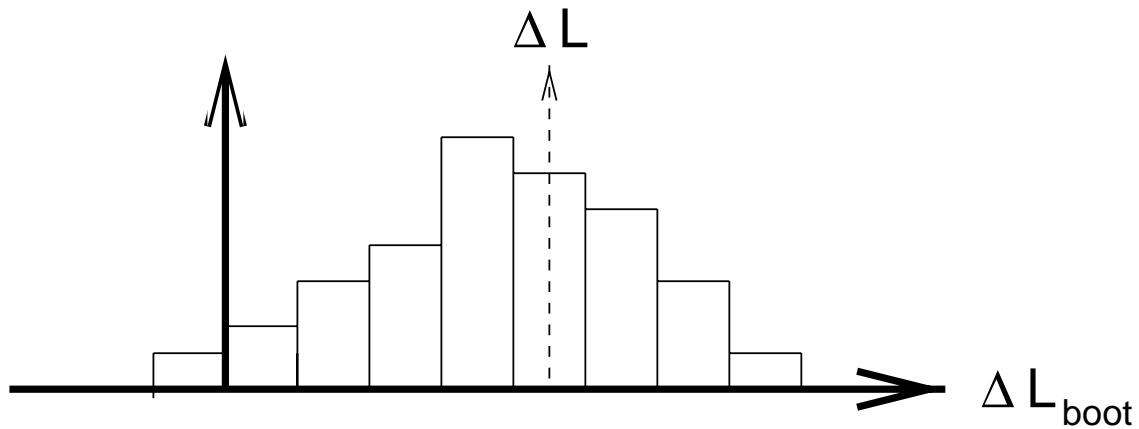

$$L_A = \ln P(D|S_A, \hat{\mathbf{w}}_A) \\ L_B = \ln P(D|S_B, \hat{\mathbf{w}}_B) \rightarrow \Delta L = L_A - L_B \neq 0?$$

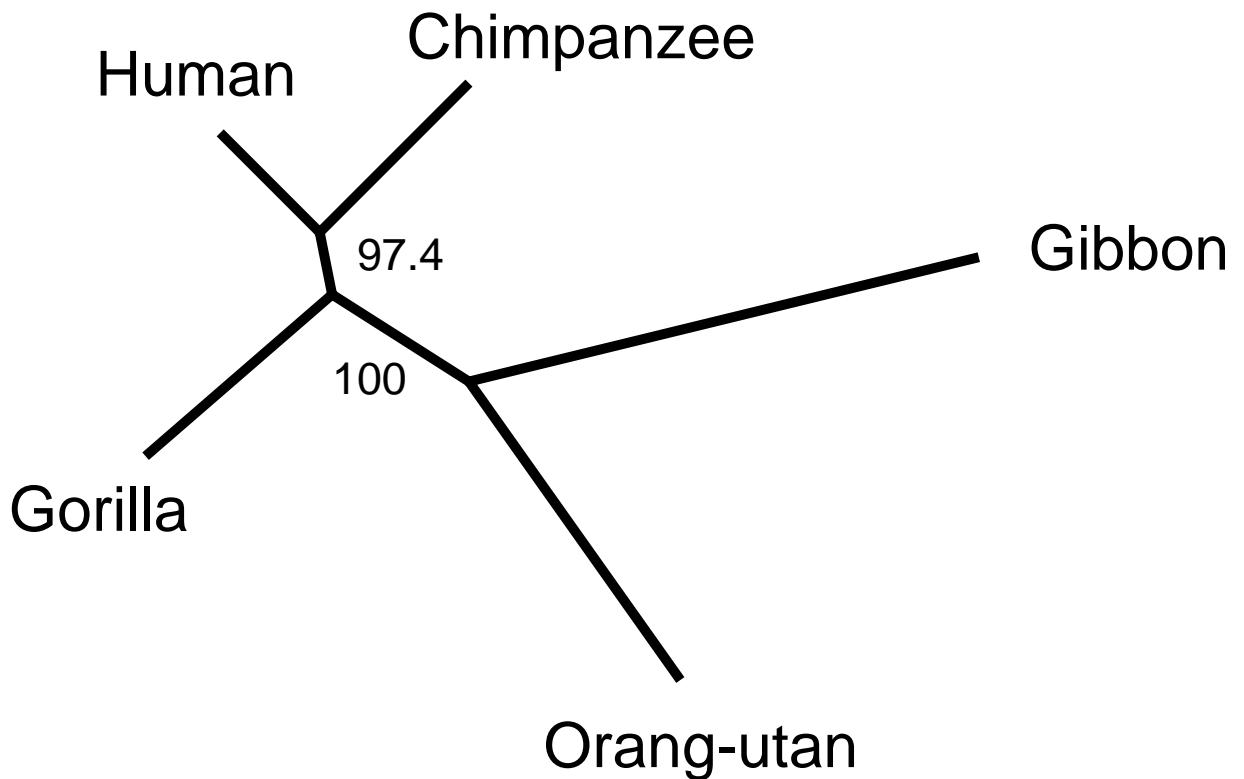

Resample with replacement from D

$$D = \{\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3, \mathbf{x}_4\} \rightarrow \begin{aligned} D_1 &= \{\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_2, \mathbf{x}_4\} \\ D_2 &= \{\mathbf{x}_2, \mathbf{x}_2, \mathbf{x}_1, \mathbf{x}_1\} \\ &\vdots \\ D_B &= \{\mathbf{x}_3, \mathbf{x}_4, \mathbf{x}_4, \mathbf{x}_1\} \end{aligned}$$

Bootstrap distribution $\{\Delta L_b\}_{b=1}^B$

Monophyletic Groups

Clade	Probability
(Human Chimp)	0.974
(Human Chimp Gorilla)	1.0
